(54) Title: **MULTIPLE-LINE PROTECTION FOR TELECOMMUNICATIONS NETWORK**

(57) Abstract

A telecommunication network uses a single backup signal transmission path to provide a backup in the event of failure of any one of a plurality of primary signal transmission paths. Both the primary signal transmission paths and the backup signal transmission path include electrical signal paths and a converter for converting the electrical signal to an optical signal path. A plurality of fiber optic switches direct a fiber optic signal from the backup transmission path to an output of a primary signal transmission path which is subject to an error detection. Simultaneously, an electrical switch redirects the incoming electrical signal of the primary signal transmission path to the backup signal transmission path.

## MULTIPLE-LINE PROTECTION FOR TELECOMMUNICATIONS NETWORK

5

I. BACKGROUND OF THE INVENTION1. Field of the Invention

This invention pertains to fiber optic transmission networks, and more particularly to such networks for use in the CATV industry. The invention pertains to a backup transmission path to be used in the event of an error in one of a plurality of primary signal transmission paths.

2. Prior Art

In a CATV network, a plurality of signal transmission paths distribute a signal from a source to a plurality of distribution points. Frequently, and particularly at the so-called "head end" of a CATV system, a plurality of radio-frequency (RF) signal paths direct a signal from a plurality of associated sources for eventual distribution to a plurality of distribution signal paths.

The primary signal transmission paths commonly include an RF signal path carried on coaxial cables and a subsequent conversion of the RF signal to an optical signal carried on fiber optic cables. The converted signal is then split into a plurality of optical signals carried on a plurality of distribution optical fibers. The primary signal path will include numerous circuit components, including a converter for converting the RF signal to an optical signal. Also, the circuit components commonly include an amplifier (such as an erbium-doped-fiber-amplifier -- EDFA) for amplifying the optical signals.

Reliability is an important design consideration in a CATV network. For example, an error can occur in a primary signal transmission. Such an error may be broadly defined to include any interruption in the signal or any unacceptable degradation of the signal. The error can be attributed to a variety of factors including damage to a fiber optic conductor or a malfunction of an RF-optic converter or EDFA. Such errors result in service interruption or poor quality service to a wide variety of subscribers who receive a signal from a plurality of distribution signal paths which are split off of the primary signal transmission path. Therefore, an error in a primary signal transmission path can result in interruption or degradation of service to a very large number of subscribers.

Since such an interruption or degradation is unacceptable in a CATV system, backup signal transmission paths are used in the event an error is detected in

a primary signal transmission path. Commonly, a prior art backup signal transmission path will include duplicate equipment (such as duplicate RF-optic converters and duplicate EDFAs) connected in parallel to the primary signal transmission path. A switch is used to switch the signal path from the primary signal transmission path to the backup signal transmission path in the event an error is detected in the primary signal transmission path. Such a switch may be a commonly used A-B fiber optic switch to switch the distribution signal paths from connection to the primary signal transmission path to the backup signal transmission path in the event of a detected error. Equipment for detecting errors and operating switches in response to detected errors are well known.

In the prior art backup signal transmission path described above, each primary signal transmission path has a dedicated backup signal transmission path. As a result, in networks having numerous primary signal transmission paths, numerous backup signal transmission paths are used. Such a network design is expensive since it requires duplicate RF-optic converters and duplicate EDFA amplifiers for each primary signal transmission path. Such equipment is very expensive and it is unfortunate that a large capital outlay must be expended for equipment intended to be idle during normal operations and intended to be used only in the rare event of an error detected on a primary signal transmission path.

Even though an error on a primary signal transmission path is a low-probability event, the consequences of such an error (disruption or unacceptable degradation of service to numerous subscribers) warrants the presence of a backup signal transmission path. Since the probability of an error in a primary signal transmission path is low, the probability of simultaneous errors in more than one primary signal transmission path is extremely low. As a result, a single backup signal transmission path could be used as a backup to numerous primary signal transmission paths. It is an object of the present invention to provide for a fiber optic transmission network having a plurality of primary signal transmission paths supported by a single backup signal transmission path. It is also an object of the present invention to provide such a backup signal transmission path with a network design which is of low cost and susceptible to fast operation to switch from a primary signal transmission path to the backup signal transmission path.

## II. SUMMARY OF THE INVENTION

According to a preferred embodiment of the present invention, a fiber optic transmission network includes a plurality of primary signal transmission paths. Each of the primary signal transmission paths includes an electrical signal path and

circuit components for converting a signal from the electrical signal path to an optical signal on a fiber optic path. The optical signal is passed to a distribution fiber path for eventual distribution to end users. The network includes a backup signal transmission path having circuit components including a converter for  
5 receiving an electrical signal from any one of the electrical signal paths of the primary signal transmission paths and converting the electrical signal to an optical signal on a backup fiber optic path. An electrical switch switches a selected one of the electrical signal paths to the backup signal transmission path in the event of a detected error. An optical switching circuit disconnects a distribution fiber path  
10 associated with the switched electrical signal path and connects the associated distribution fiber path to the backup fiber optic path.

### III. BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic representation of a telecommunications network having four primary signal transmission paths and single backup signal transmission  
15 path according to the present invention and showing signal paths when no error is detected along any of the primary signal transmission paths;

FIG. 2 is the view of FIG. 1 showing signal paths when an error is detected on a first of the plurality of primary signal transmission paths;

FIG. 3 is the view of FIG. 1 showing signal paths when an error is  
20 detected in a second of the primary signal transmission paths;

FIG. 4 is the view of FIG. 1 showing circuit paths when an error is detected in a third of the primary signal transmission paths;

FIG. 5 is the view of FIG. 1 showing signal paths when an error is detected in a fourth of the primary signal transmission paths;

FIG. 6 is a more detailed schematic view of a two-by-two switching  
25 component for use in the network of the present invention and with the switch of the switching component shown in a normal mode;

FIG. 7 is the view of FIG. 6 with the switch shown in a switched  
mode;

FIG. 8 is a more detailed schematic view of a one-by-two switching  
30 component for use in the network of the present invention and with a switch shown in a normal mode of operation; and

FIG. 9 is the view of FIG. 8 with the switch shown in a switched mode of operation.

#### IV. DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the various drawing figures in which identical elements are numbered identically throughout, a description of the preferred embodiment of the present invention will now be provided.

FIG. 1 schematically illustrates a CATV network 10 as including four primary signal transmission paths 12<sub>1</sub> - 12<sub>4</sub>. It will be appreciated that the illustration of four primary signal transmission paths is done for the purpose of illustrating the invention and such a network 10 may include more or less of such paths. The network 10 includes a single backup signal transmission line 12'.

Each of the primary paths 12<sub>1</sub>-12<sub>4</sub> includes an electrical (radio frequency) signal path 14<sub>1</sub>-14<sub>4</sub>. Connected in series with the electrical signal paths 14<sub>1</sub>-14<sub>4</sub> are converters 16<sub>1</sub>-16<sub>4</sub> for receiving an electrical signal from the RF paths 14<sub>1</sub>-14<sub>4</sub> and converting the electrical signal to an optical signal carried on a fiber optic path 19<sub>1</sub>-19<sub>4</sub>. The fiber optic paths 19<sub>1</sub>-19<sub>4</sub> each include EDFA amplifiers 18<sub>1</sub>-18<sub>4</sub> for amplifying the optical signal carried on the paths 19<sub>1</sub>-19<sub>4</sub>.

Each of the primary transmission paths 12<sub>1</sub>-12<sub>4</sub> includes a fiber optic switch component 20<sub>1</sub>-20<sub>4</sub> and a distribution fiber path 15<sub>1</sub>-15<sub>4</sub>. The distribution fiber path 15<sub>1</sub>-15<sub>4</sub> is connected to a fiber optic splitter 22<sub>1</sub>-22<sub>4</sub> for splitting an optical signal on distribution path 15<sub>1</sub>-15<sub>4</sub> into a plurality of branch fiber optic paths 24a<sub>1</sub>-24d<sub>1</sub>, 24a<sub>2</sub>-24d<sub>2</sub>, 24a<sub>3</sub>-24d<sub>3</sub> and 24a<sub>4</sub>-24d<sub>4</sub>.

Each of the RF signal paths 14<sub>1</sub>-14<sub>4</sub> passes through a radio frequency switch 26 having internal switching components 26a, 26b, 26c, and 26d which, in a normal mode (illustrated in FIG. 1), pass a signal uninterrupted to an associated converter 16<sub>1</sub>-16<sub>4</sub>. Each of the switching mechanisms 26a-26d is selectively and individually switchable to a switched position for directing a selected one of the signals on the RF paths 14<sub>1</sub>-14<sub>4</sub> to the backup signal transmission path 12'. The backup signal transmission path 12' includes an RF signal path 14' connected to a fiber optic converter 16' which converts the electrical signal to a fiber optic signal carried on a backup fiber optic path 19'. An EDFA amplifier 18' is associated with the fiber optic path 19'.

For purposes that will be more fully discussed, each of the switches 20<sub>1</sub>-20<sub>4</sub> has an associated feedback line 28<sub>1</sub>-28<sub>4</sub> to provide a signal to the RF switch 26 in response to the presence or absence of an error on the primary signal path 12<sub>1</sub> - 12<sub>4</sub>.

The signal components 20<sub>2</sub>-20<sub>4</sub> are identical switching components containing two-by-two optical switches. For reasons that will be apparent, switching component 20<sub>1</sub> contains a one-by-two optical switch. Since primary signal

transmission path 12<sub>1</sub> is identical in all respects to paths 12<sub>2</sub>-12<sub>4</sub> but for switch 20<sub>1</sub>, path 12<sub>1</sub> may conveniently be referred to as a terminal primary signal transmission path indicating that it is the last primary signal transmission path 12<sub>1</sub> having its switch 20<sub>1</sub>, arranged in series with switches 20<sub>2</sub>-20<sub>4</sub> from the backup signal transmission path 12' as will be described.

A two-by-two switching component 20<sub>2</sub> is more fully schematically illustrated in FIGS. 6 and 7. It will be appreciated that switching components 20<sub>3</sub> and 20<sub>4</sub> are identical to component 20<sub>2</sub> and do not require separate description. Subscript designation (e.g., 28<sub>2</sub>, 60<sub>2</sub>) will be used to reference components of a specifically identified switch 20<sub>2</sub>. When collectively or generally referencing to components of switch 20<sub>2</sub>-20<sub>4</sub>, the subscripts will be omitted in this description (e.g., 28, 60).

The switching component 20<sub>2</sub> includes a switch housing 50<sub>2</sub> and an error detector/controller 60<sub>2</sub>. The switch housing 50<sub>2</sub> contains an internal splitter 52<sub>2</sub> for splitting a signal carried on the fiber optic path 19<sub>2</sub> with a small portion of this signal passed to monitor signal path 54<sub>2</sub>. The remainder of the signal from path 19<sub>2</sub> is passed to a primary input 56a<sub>2</sub> of a two-by-two fiber optic switch 56<sub>2</sub>. A secondary input 56b<sub>2</sub> of switch 56<sub>2</sub> is connected to a bypass fiber optic cable 17<sub>2</sub>.

A primary output 56a'<sub>2</sub> of switch 56<sub>2</sub> is connected to the distribution fiber path 15<sub>2</sub>. The secondary output 56b'<sub>2</sub> of switch 56<sub>2</sub> is connected to a bypass fiber optic cable 17<sub>1</sub>. The monitor fiber 54<sub>2</sub> is passed to the controller 60<sub>2</sub> which monitors the presence and integrity of the signal on fiber 54<sub>2</sub>.

In the event of an interruption or unacceptable degradation of the signal, the controller 60<sub>2</sub> transmits an error signal along feedback lines 28<sub>2</sub> and 28a<sub>2</sub>. In the absence of such detected error or unacceptable degradation, the controller 60<sub>2</sub> transmits a no-error signal along feedback lines 28<sub>2</sub>, 28a<sub>2</sub>.

FIG. 6 illustrates the switching component 20<sub>2</sub> in a normal mode of operation where the switch 56<sub>2</sub> directs a signal from the primary input 56a<sub>2</sub> to the primary output 56a'<sub>2</sub> and further directs a signal from the secondary input 56b<sub>2</sub> to the secondary output 56b'<sub>2</sub>. FIG. 7 illustrates the switching component 20<sub>2</sub> in a switched mode where the primary input 56a<sub>2</sub> is connected to the secondary output 56b'<sub>2</sub> and the secondary input 56b<sub>2</sub> is connected to the primary output 56a'<sub>2</sub>.

As mentioned, and for reasons that will become apparent, switching component 20<sub>1</sub> differs from component 20<sub>2</sub> only in that the internal switch 56<sub>1</sub> is a one-by-two switch with a primary input 56a<sub>1</sub> normally connected to a primary output 56a'<sub>1</sub>. In such a mode, the secondary input 56b<sub>1</sub> is terminated. All other components of switch component 20<sub>1</sub> are identical to those of switch component 20<sub>2</sub> and are identically numbered except for the addition of a distinguishing subscript. FIG. 9

illustrates switching component 20<sub>1</sub> in a switched mode where the primary input 56a<sub>1</sub> is terminated and the secondary input 56b<sub>1</sub> is connected to the primary output 56a'<sub>1</sub>.

As illustrated in the drawings, each of the fiber optic paths 19<sub>1</sub>-19<sub>4</sub> of the primary signal transmission paths 12<sub>1</sub> - 12<sub>4</sub> are connected to the primary inputs 56a of each of the switching components 20<sub>1</sub>-20<sub>4</sub>. The distribution fiber paths 15<sub>1</sub>-15<sub>4</sub> are connected to the primary outputs 56a' of each of the switching components 20<sub>1</sub>-20<sub>4</sub>.

The backup fiber optic path 19' is connected to the secondary input 56b<sub>4</sub> of switching component 20<sub>4</sub>. Bypass fiber optic cable 17<sub>3</sub> connects the secondary output 56b'<sub>4</sub> of switching component 20<sub>4</sub> to the secondary input 56b<sub>3</sub> of switching component 20<sub>3</sub>.

Bypass fiber optic cable 17<sub>2</sub> connects the secondary output 56b'<sub>3</sub> of switching component 20<sub>3</sub> to the secondary input 56b<sub>2</sub> of switching component 20<sub>2</sub>. Similarly, fiber optic cable 17<sub>1</sub> connects the secondary output 56b'<sub>2</sub> of switching component 20<sub>2</sub> with the secondary input 56b<sub>1</sub> of switching component 20<sub>1</sub>.

With the network thus described, a plurality of sources (not shown) transmit a plurality of RF signals across individual lines 14<sub>1</sub>-14<sub>4</sub>. In the absence of an error, a no-error mode signal is passed over feedback 28<sub>1</sub>-28<sub>4</sub>. Therefore, switches 26a-26d are in their normal mode illustrated in FIG. 1 such that the signals on lines 14<sub>1</sub>-14<sub>4</sub> are passed to their associated converters 16<sub>1</sub>-16<sub>4</sub> for conversion to optical signals on fiber optic cables 19<sub>1</sub>-19<sub>4</sub>. The fiber optic signals are amplified by amplifiers 18<sub>1</sub>-18<sub>4</sub>.

In addition to controlling RF switch 26, the controllers 60 control switching components 20<sub>1</sub>-20<sub>4</sub>. Namely, while a no-error signal is passed along lines 28<sub>1</sub>-28<sub>4</sub>, a no-error signal is also passed along feedback lines 28a such as lines 28a<sub>1</sub> and 28a<sub>2</sub> in FIGS. 7-9 to hold switches 20<sub>1</sub>-20<sub>4</sub> in their normal unswitched mode of operation. With each of the switches 20<sub>1</sub>-20<sub>4</sub> in the normal mode of operation, the signals on fiber optic paths 19<sub>1</sub>-19<sub>4</sub> are passed to associated distribution fibers 15<sub>1</sub>-15<sub>4</sub> for ultimate splitting among the associated branch fibers 24a<sub>1</sub>-24d<sub>1</sub>, 24a<sub>2</sub>-24d<sub>2</sub>, 24a<sub>3</sub>-24d<sub>3</sub>, and 24a<sub>4</sub>-24d<sub>4</sub>.

While the signals are passing through the unswitched switching components 20<sub>1</sub>-20<sub>4</sub>, small portions of the signals are being passed by the splitters 52 to the controllers 60. As long as no signal interruption or unacceptable signal degradation is determined by the controller 60, the no-error signal is passed by the feedback lines 28, 28a to the RF switch 26 and fiber optic switches 20<sub>1</sub>-20<sub>4</sub>.

FIG. 2 illustrates a system response in the event an error is detected on the primary transmission line 12<sub>1</sub>. In such an event, the controller 60<sub>1</sub> transmits

an error signal across feedback lines 28<sub>1</sub> and 28a<sub>1</sub> to the RF switch 26 and the fiber optic switch 56<sub>1</sub>. In response to an error signal on line 28<sub>1</sub>, the RF switch 26 is activated such that internal switch 26a is switched to redirect the RF signal from RF conductor 14<sub>1</sub> to the RF conductor 14' of the backup transmission circuit 12'.

- 5 Simultaneously, an error signal is sent across line 28a<sub>1</sub> to switch 56<sub>1</sub> causing the internal switch 56<sub>1</sub> to switch to the switched mode illustrated in FIG. 9. Switches 20<sub>2</sub>-20<sub>4</sub> remain in the normal, unswitched mode. As a result of this operation, the signal on RF conductor 14<sub>1</sub> completely bypasses the primary transmission path 12<sub>1</sub> and is redirected to the backup transmission path 12'. On backup path 12', the signal
- 10 is converted to a fiber optic signal at converter 16' and subsequently amplified by amplifier 18'. The amplified backup signal is passed along the backup fiber optic path 19' to the secondary input 56b<sub>4</sub> of switch 20<sub>4</sub>. Since switches 20<sub>2</sub>-20<sub>4</sub> remain in the unswitched mode, the signal passes through the switches 20<sub>2</sub>-20<sub>4</sub> via fiber optic cables 17<sub>2</sub> and 17<sub>3</sub>. From switch 20<sub>2</sub>, the backup signal is passed through fiber optic
- 15 cable 17<sub>1</sub> to the secondary input 56b<sub>1</sub> of switch 20<sub>1</sub>. Since switch 20<sub>1</sub> has been put in the switched mode of FIG. 9, the signal is passed to distribution fiber 15<sub>1</sub>. Therefore, in the event of an error on line 12<sub>1</sub>, the RF signal on path 14<sub>1</sub> passes through the backup signal transmission path 12' and is subject to the same fiber optic conversion and amplification functions normally performed by converter 16<sub>1</sub> and
- 20 amplifier 18<sub>1</sub> and now performed by converters 16' and amplifier 18'. The converted and amplified signal is then distributed to distribution fiber 15<sub>1</sub>. As a result, subscribers served by branch fibers 24a<sub>1</sub>-24d<sub>1</sub> receive a signal as if no error or degradation had occurred on signal transmission line 12<sub>1</sub>. In the event the cause of the error is corrected on primary transmission line 12<sub>1</sub>, the switch 20<sub>1</sub> reverts to its
- 25 normal mode of operation illustrated in FIG. 8 and switch 26a also reverts to normal mode operation such that the signal from RF line 14<sub>1</sub> passes through transmission line 12<sub>1</sub> and avoids the backup signal path 12'.

FIG. 3 illustrates operation of the network in the event an error occurs on line 12<sub>2</sub>. In such an event, the error is detected by controller 60<sub>2</sub> which sends an

30 error message across feedback lines 28<sub>2</sub> and 28a<sub>2</sub>. In response to the error message on feedback line 28<sub>2</sub>, the RF switch 26 switches internal switch 26b for the RF signal on conductor 14<sub>2</sub> to bypass the primary transmission path 12<sub>2</sub> and be redirected to the backup transmission path 12'.

In response to the error signal on feedback line 28a<sub>2</sub>, switch 20<sub>2</sub>

35 switches to the switched mode of operation illustrated in FIG. 7 while switches 20<sub>1</sub> and 20<sub>3</sub>, 20<sub>4</sub> remain in their unswitched, normal mode of operation. As a result, the signal on RF conductor 14<sub>2</sub> is converted and amplified by the backup transmission path 12' and the converted and amplified signal flows through switches 20<sub>3</sub> and 20<sub>4</sub>

to the secondary input 56b<sub>2</sub> of switch 20<sub>2</sub>. Since switch 20<sub>2</sub> has been switched, the secondary input 56b<sub>2</sub> is connected to the distribution fiber 15<sub>2</sub> so the signal passes to the subscribers on branch lines 24a<sub>2</sub>-24d<sub>2</sub>. Again, once the error on transmission path 12<sub>2</sub> has been corrected, switches 26b and 20<sub>2</sub> revert to the normal mode of operation illustrated in FIGS. 1 and 6.

FIGS. 4 and 5 illustrate operation of the network 10 in the event an error is detected on primary transmission lines 12<sub>3</sub> and 12<sub>4</sub>, respectively. The mode of operation is identical to that illustrated in FIG. 3. Namely, in the event of an error on line 12<sub>3</sub>, switches 26c and 20<sub>3</sub> are switched from their normal mode of operation to their switched mode of operation. As a result, the signal on line 14<sub>3</sub> passes through the backup signal transmission path 12' and is converted and amplified and directed to distribution path 15<sub>3</sub>. Similarly, FIG. 5 illustrates that an error in primary transmission line 12<sub>4</sub> results in switches 26d, 20<sub>4</sub> being switched with the signal on line 14<sub>4</sub>, is passed through the backup transmission path 12', and converted and amplified and redirected to path 15<sub>4</sub>.

With the present invention, a single backup transmission path 12' serves as a backup in the event of an error detected on any one of a plurality of primary transmission signal paths 12<sub>1</sub>-12<sub>4</sub>. The present invention can provide a backup to only one of the plurality of primary transmission signal paths 12<sub>1</sub>-12<sub>4</sub> at any one time. However, an error in any one of such paths 12<sub>1</sub>-12<sub>4</sub> is a very low probability and multiple errors on multiple paths are, accordingly, extremely remote possibilities.

The signal from the backup transmission path 12' passes through multiple switches (for example, switches 20<sub>2</sub>-20<sub>4</sub>) before finally passing to switch 20<sub>1</sub> in the event of an error on line 12<sub>1</sub>. Since fiber optic switches such as switches 20<sub>2</sub>-20<sub>4</sub> can result in signal loss, amplifier 18' is preferably a higher gain amplifier than amplifiers 18<sub>1</sub>-18<sub>4</sub> in order to make up for signal losses of a signal passing through any of fiber optic switching components 20<sub>1</sub>-20<sub>4</sub>. Commonly, amplifiers 18<sub>1</sub>-18<sub>4</sub> are 17 dBm amplifiers and switches such as 20<sub>2</sub>-20<sub>4</sub> are about 0.2 dBm loss switches. Commercially available EDFA amplifiers are available at 24 dBm gain (and higher). Therefore, with amplifier 18' selected as a 24 dBm gain amplifier and with amplifiers 18<sub>1</sub>-18<sub>4</sub> selected as 17 dBm amplifiers, the combined loss through switches 20<sub>2</sub>-20<sub>4</sub> should not exceed 7 dBm. However, since switches 20<sub>2</sub>-20<sub>4</sub> are available at 0.2 dBm loss, the theoretical maximum number of primary lines which can be served by backup transmission path 12' will be thirty-five primary transmission paths 12<sub>1</sub> - 12<sub>4</sub>. It will be appreciated that this represents a theoretical maximum. As the number of primary transmission paths 12<sub>1</sub> - 12<sub>4</sub> increases with the paths being served by a single backup transmission path 12', the probability of

having two primary transmission paths  $12_1 - 12_4$  in an error mode increases. As a result, the number of primary transmission paths  $12_1 - 12_4$  which can be served by a single backup path  $12'$  is also a function of a system designer's risk aversion to the remote probability that more than one primary signal transmission path  $12_1 - 12_4$  will be under an error condition at any one time.

With the present invention, the network 10 has dramatically reduced costs compared with a prior art network design where each primary transmission paths had a dedicated backup transmission path. The prior art system virtually doubles the amount of equipment and expense required over a system that had no backup transmission paths. The expense is particularly great with respect to EDFA amplifiers which are very expensive items. Instead of doubling expense, the present invention adds only a single backup transmission path  $12'$  to serve multiple primary transmission paths  $12_1 - 12_4$ . The network 10 retains high reliability and high quality by switching not only the optical signals but also RF sources. The system 10 can achieve fast switching operation by performing one-step switching, no matter which primary line is out of service. Further, the present invention achieves the desired benefits with decreased optical light attenuation by avoiding excessive use of splitters. Also, once the system is in place for a given number of primary transmission lines, it can be readily expanded to have the single backup transmission  $12'$  service additional primary transmission paths. Finally, all components of the network 10 (such as switches  $20_1 - 20_4$  with monitor capabilities, a controller 60 and RF switches 26) are commercially available items making the present invention susceptible to rapid implementation.

Having disclosed the present invention in a preferred embodiment, it will be appreciated that modifications and equivalents of the disclosed concepts may readily occur to one of ordinary skill in the art. It is intended that such modifications and equivalents shall be included within the scope of the claims which are appended hereto.

What is claimed is:

1. A fiber optic transmission network comprising:  
a plurality of primary signal transmission paths each having:  
5 an electrical signal path;  
circuit components including a converter for receiving an electrical  
signal from said electrical signal path and converting said electrical signal to an  
optic signal on a fiber optic path;  
a fiber optic switch component having:  
10 primary and secondary inputs;  
primary and secondary outputs;  
an optical switch for selectively switching between a primary mode  
with said primary input and output connected and a secondary mode with said  
secondary input and output connected;  
15 said primary input connected to said fiber optic path and said primary  
output connected to a distribution fiber path;  
a backup signal transmission path having circuit components  
including a converter for receiving an electrical signal from any one of said electrical  
signal paths as an input and converting said signal to an optic signal on a backup  
20 fiber optic path;  
said backup fiber optic path connected to a secondary input of a  
selected one of said fiber optic switch components;  
individual ones of said secondary outputs of said fiber optic switch  
components connected to secondary inputs of individual ones of said fiber optic  
25 switch components;  
an electrical switch for switching a selected one of said electrical  
signal paths to said backup signal transmission path;  
a controller for detecting an error in an individual one of said primary  
signal transmission paths and, in response to said detection:  
30 shifting said optical switch of said individual one from said primary  
mode to said secondary mode; and  
operating said electrical switch to switch said electrical signal path of  
said individual one to said backup signal transmission path.
- 35 2. A fiber optic transmission network according to claim 1 further  
comprising:  
a terminal primary signal transmission path having:  
an electrical signal path;

circuit components including a converter for receiving a signal from said electrical signal path and converting said signal to an optic signal on a fiber optic path;

- 5                   a fiber optic switch components having:  
primary and secondary inputs;  
a primary output;  
an optical switch for selectively switching between a primary mode with said primary input and output connected and a secondary mode with said secondary input and said primary output connected;
- 10                  said primary input connected to said fiber optic path and said primary output connected to a distribution fiber path;  
said secondary input connected to a secondary output of one of said optical switch of said primary signal transmission paths.

- 15                  3.     A fiber optic transmission network comprising:  
a plurality of primary signal transmission paths each having:  
an electrical signal path;  
circuit components including a converter for receiving an electrical signal from said electrical signal path and converting said electrical signal to an optic signal on a fiber optic path;
- 20                   a distribution fiber path;  
a backup signal transmission path having circuit components including a converter for receiving an electrical signal from any one of said electrical signal paths as an input and converting said electrical signal to an optic signal on a backup fiber optic path;
- 25                   an electrical switch for switching a selected one of said electrical signal paths to said backup signal transmission path;  
an optical switching circuit for disconnecting a selected one of said distribution fiber paths and connecting said selected one to said backup fiber optic path;
- 30                   a controller for detecting an error in an individual one of said primary signal transmission paths and, in response to said detection:  
operating said optical switching circuit to disconnect said distribution fiber path of said individual one and connecting said distribution fiber path of said individual one to said backup fiber optic path; and
- 35                   operating said radio frequency switch to switch said radio frequency path of said individual one to said backup signal transmission path.

4. A fiber optic transmission network according to claim 3 wherein:  
said optical switching circuit comprises a plurality of fiber optic  
switch components associated with each of said primary signal paths with said fiber  
optic switch components having:

- 5                   primary and secondary inputs;  
                  primary and secondary outputs;  
                  an optical switch for selectively switching between a primary mode  
with said primary input and output connected and a secondary mode with said  
secondary input and output connected;
- 10                  said primary input connected to said fiber optic path and said primary  
output connected to said distribution fiber path;  
                  said fiber optic path of said backup signal transmission path  
connected to a secondary input of a selected one of said fiber optic switch  
components;
- 15                  individual ones of said secondary outputs of said fiber optic switch  
components connected to secondary inputs of individual ones of said fiber optic  
switch components;
- said controller operating said optical switching circuit by shifting said  
optical switch of said individual one from said primary mode to said secondary  
20   mode.

5. A fiber optic transmission network according to claim 3 wherein said  
optical switching circuit comprises a plurality of fiber optic switches each associated  
with an individual one of said fiber optic paths of said primary signal transmission  
25   paths;

- said fiber optic switches having normal paths for a signal on an  
associated primary signal transmission path to pass to an associated distribution  
path;
- said fiber optic switches further having switched paths for said switch  
30   to receive a fiber optic signal from a different one of said switches and pass said  
signal to said associated distribution path.

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

### \* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family
